# Overview

- Characteristics of state biomonitoring data sets
- Potential signals
- Fixed stations vs probabilistic approach
- Taxonomy issues
- Closing thoughts

# Bioassessment Data Sets

- Design based on monitoring objectives
  - CWA mandates
- Three main questions:
  - Status of aquatic resources, various scales
  - Impairment decisions (based on comparison to reference locations)
  - Comparison of condition to previous assessment

**Spatial evaluations emphasized**

# Now we want to incorporate climate change evaluation

- Emphasize long-term temporal trends
- Availability of adequate temporal data – duration and frequency
- “Regional” consistency of trends – single (fixed) location vs population of “representative” locations
- Are the trends real, or artifacts of methods changes over time (taxonomy, sampling procedures)?
- Types and extent of covariables

# Availability of Adequate Long Term Data

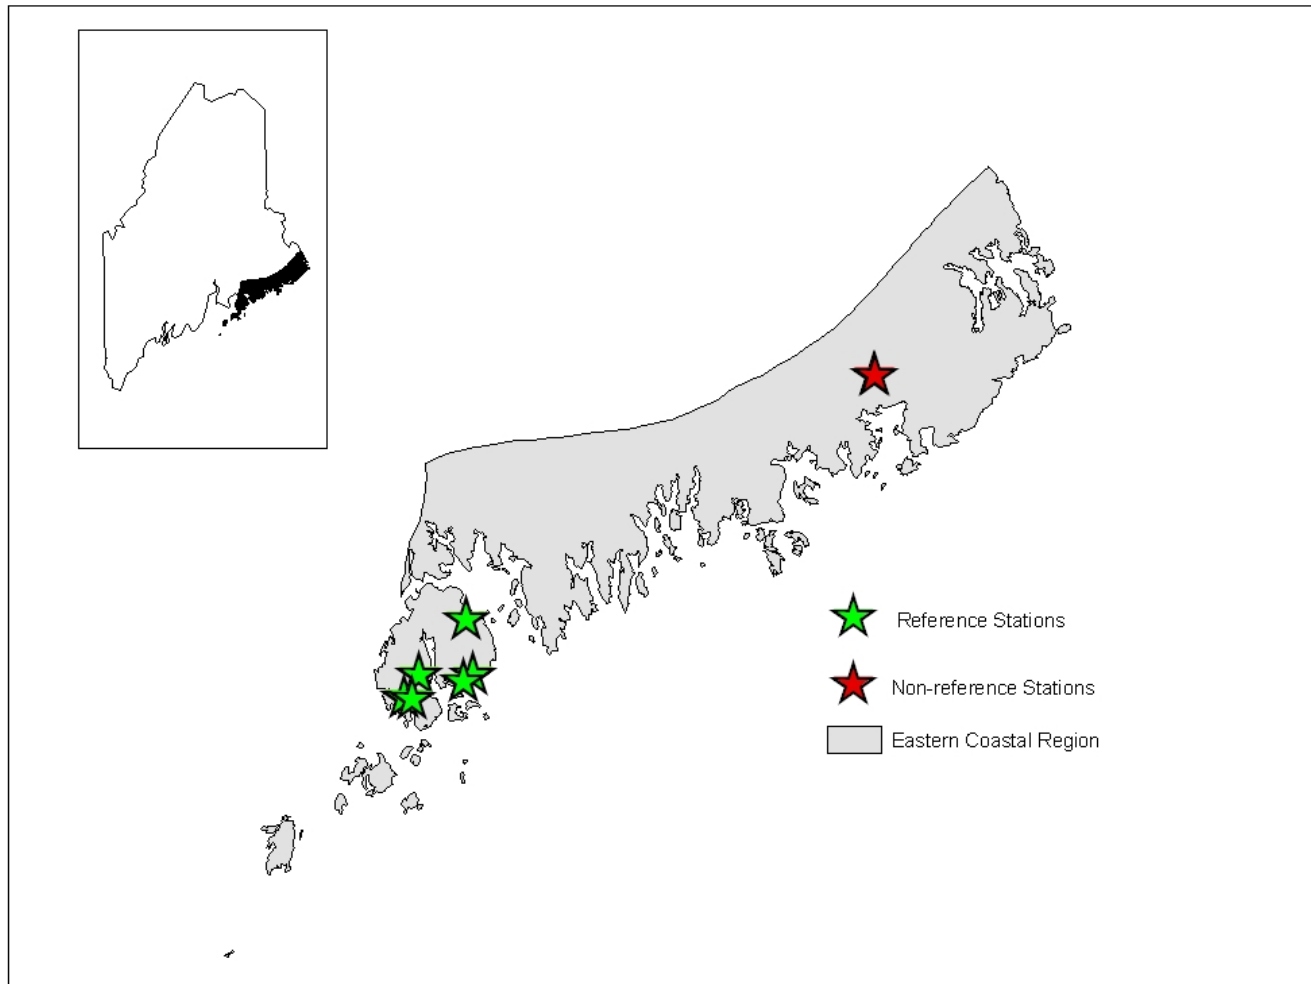

## Maine Example

# Years Sampled	Reference Stations (AA & A)	Non-Reference (B & C)	Not Classified
10-19	2	4	0
5-9	10	30	0
2-4	94	183	0
1	116	302	1

# Maine Sampling Stations

## In Eastern Coastal Region (Ecoregion 82)

(6 of 8 are reference locations)

# Maine E Coast Species

# Sheepscot River

**Year is strongest factor**

# Availability of Adequate Long Term Data

## Utah Example

# Years Sampled	Reference Stations	Unclassified Stations
10-19	4	3
5-9	4	29
2-4	7	178
1	54	300

# Utah Reference Stations

## Legend

**Stations - Utah DEQ (Years Sampled, Ref sites)**

**MapClass**

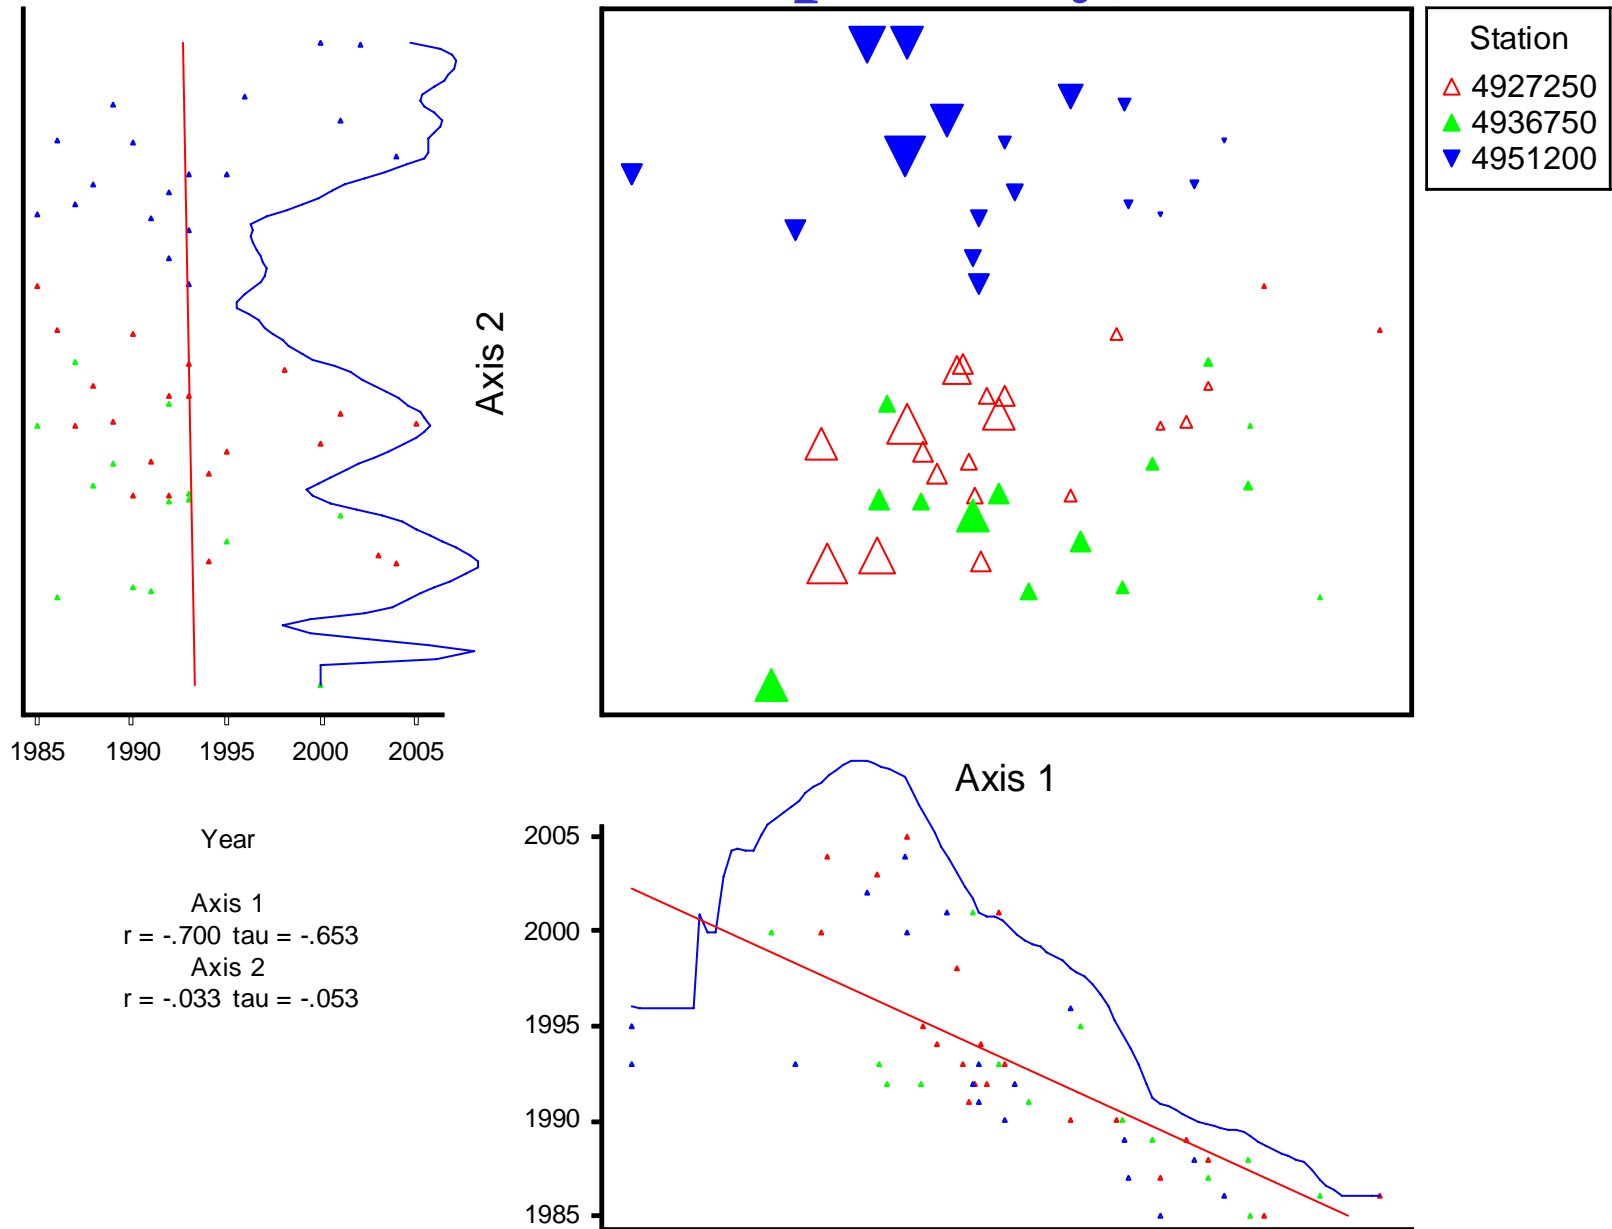

REF (10-19)

REF (5-9)

REF (1-4)

States

# Utah – 3 reference locations/2 ecoregions (fall samples only)

**Are observed long-term trends  
real or artifacts?**

# Taxonomy

- Changes in taxonomists
- Changes in level of detail
- Increasing knowledge (better keys)

# What was done to “fix” taxonomic differences? – Utah Example

- Lab changed in 1998
- Machine-check for taxa occurring early but not later, and visa versa
- Findings reviewed by expert, cross-checked with active local taxonomist

# What was done to “fix” taxonomic differences? – Utah Example

Found examples of:

- Taxa (genera, species) called different names between time periods/labs (misnamed, or name changes)
- Taxa left at family (or other higher level) by one lab, taken to finer level by another
- More of a taxon left as “unidentified” at one time or another

# What was done to “fix” taxonomic differences? – Utah Example

- Often summed to uniform higher level (genus from species, family from genera) to remove “artifact” differences in taxon abundances, richness, etc over time
- Sometimes defined an OTU to combine names not reliably differentiated, but not lose other valid genus/species information in that family

## Other Factors

- Sample splitting and processing may have changed, search for “big and rare” taxa added
- Reporting of replicate counts (by rep, or summed for station) varied
- Poor documentation on whether counts for whole samples (reps combined) were averages or sums

# Utah DEQ Bioassessment Data, Benthic Invertebrates, 1977-2005, original data

Multivariate  
community  
analysis (NMDS)

Change in  
taxonomy lab  
reflected as  
change in  
community  
composition

# Utah DEQ Bioassessment Data, Benthic Invertebrates, 1977-2005, “OTU” corrections

OTU “fixes”  
eliminated  
artifact of  
community  
change due to lab  
change

# Could “valid” long-term trends still be found?

Station (Utah references)	Total Taxa Richness	
	Pre-OTU Fix	Post-OTU Fix
4927250	143	81
4936750	122	69
4951200	120	74

# Could “valid” long-term trends still be found?

Taxa richness comparison Pre- and Post-OTU for Station 4936750, Utah

Taxa richness comparison Pre- and Post-OTU for Station 4951200, Utah

# Valid taxa trends have also been found

Simuliidae at Site 4927250

*Simuliidae*

Lepidostoma at Site 4936750

*Lepidostoma*

Baetidae at Site 4951200

*Baetidae*

# Closing Thoughts

- Monitoring design issues:
  - fixed stations – representative of ecoregion?
  - Random stations: low power for trends
- Single stations have lower variability over time than multiple stations
- Single design won't answer all questions
  - Fixed stations for trends
  - Random stations to characterize basins, ecoregions

# Closing Thoughts

- Much time spent in reviewing and “fixing” long-term data sets, even those that are well QC’d. This is critical – time well spent
- Hemispheric climate drivers (ENSO, NAO) may account for interannual variation – could enhance confidence in long-term trends
- Long-term, continuous monitoring of temperature and flow are critical, and too often lacking.
